# Azure Development

# Azure Resource Groups

- Resources in a resource group should share the same lifecycle
- Each resource can only exist in one resource group
- Resources can be added or removed to a resource group at any time
- Resources can be moved from one resources group to another
- Resource groups can contain resources that reside in different regions
- Resources can interact with resources in other resources groups

# Resource Group Management

- Tags
- Locks
- Access Control (IAM)
- Policies

# Sample Resource Group

- Ms-net-rg
- Purpose: Isolate the Virtual networks
- Need: Prevent unwanted changes to any of the network resources
- Admin: It will deploy and maintain RG
- Notes: Resources in other RGs will use the resources int this group
- Dept: IT
- Owner: Onur YUKSEKTEPELI

# Demo

- Creating a Resource

# Azure Resource Tags

- Logically organize resources. Each tag has a name and a value. Allows related resources from different resource groups to be identified. Organize by billing and management.

# TAG Rules

- Tags are NOT inherited
- Names can't contain these characters: <, >, %, &, \, ?, /
- Tag name is limited to 512 characters
- Tag value is limited to 256 characters

# Demo

- Create Tag

# Resource Group Locks

- Prevent accidental deletion or changes to resources in resource groups. Consists of two locks:
  - CanNotDelete
  - ReadOnly

# Demo

- Create Resource Locks

# Access Control (IAM)

- A system that provides fine-grained access Management of resources in Azure. Grant only the amount of Access to users needed to perform their jobs

# Demo

- Access Control (IAM)

# Azure Policy

- Allows you to manage and prevent IT issues with policy definitions that enforce rules and effects for your resources. Policies allow you to keep compliant with corporate standards and SLAs.

# Demo

- Azure Policy

# Azure Compute

Azure Champ

# Azure Compute

- Azure Compute Unit

The concept of the Azure Compute Unit (ACU) provides a way of comparing compute (CPU) performance across Azure SKUs. This will help you easily identify which SKU is most likely to satisfy your performance needs. ACU is currently standardized on a Small (Standard\_A1) VM being 100 and all other SKUs then represent approximately how much faster that SKU can run a standard benchmark.

# Azure Compute Unit(ACU)

SKU Family	ACU \ vCPU	vCPU: Core
A0	50	1:1
A1 - A4	100	1:1
A5 - A7	100	1:1
A1_v2 - A8_v2	100	1:1
A2m_v2 - A8m_v2	100	1:1
A8 - A11	225*	1:1
D1 - D14	160 - 250	1:1
D1_v2 - D15_v2	210 - 250*	1:1
DS1 - DS14	160 - 250	1:1
DS1_v2 - DS15_v2	210 - 250*	1:1
D_v3	160 - 190*	2:1***
Ds_v3	160 - 190*	2:1***
E_v3	160 - 190*	2:1***
Es_v3	160 - 190*	2:1***
F2s_v2 - F72s_v2	195 - 210*	2:1***
F1 - F16	210 - 250*	1:1
F1s - F16s	210 - 250*	1:1
G1 - G5	180 - 240*	1:1
GS1 - GS5	180 - 240*	1:1
H	290 - 300*	1:1

# Azure Virtual Machines

	General Purpose	Compute Optimized	Memory Optimized	Storage Optimized	GPU	High Performance Compute
Type	DC, Av2, Dv2, Dv3, B, Dsv3	Fsv2, F	M, Dv2, G, Dsv2, GS, Ev3	Ls	NC, NCv2, ND, BV, NVv2	H
Description	Balanced CPU and memory	High ratio of compute to memory	High ratio of memory to compute	High disk throughput and IO	Specialized with single or multiple NVIDIA GPUs	High memory and compute power – fastest and most powerful
Uses	Testing and dev, small-med databases, low traffic web servers	Medium traffic web servers, network appliances, batch processing, app servers	Relational database services, analytics, and larger caches	Big Data, SQL, NoSQL databases	Compute intensive, graphics-intensive, and visualization workloads	Batch processing, analytics, molecular modeling, and fluid dynamics, low latency RDMA networking

# Standard vs. Premium Storage Disks

Standard Disks	Premium Disks
Backed by cost-effective HDDs	Backed by high-speed SSDs
Stored in Azure storage account	IOPS values are predictable, expected performance levels
Standard SSD (Preview) available for managed disks (dev/test/entry level production applications)	Pre-pay for all storage used (fixed disk sizes P10, 128 GB, 500 IOPs, 50 MB/sec
Standard storage provides maximum IOPS values for each VHD	

# Managed vs. Unmanaged Disks

Unmanaged Disks	Managed Disks
Original method to store VM VHDs	Azure manages the disks, so you don't have to worry about storage account level IOPS restrictions
VHDs stored as page blobs in an Azure storage account	Pre-pay for disk size (no need for SA) S10, 128 GB, 500 IOPS, 60 MB/sec
Maximum 256 TB of storage per VM	Supports Standard and Premium SSD and Standard HDD
You need to manage storage account availability	
20,000 IOPS limit across all VM disks in a standard storage account	

# Ultra SSD – the next generation of Azure Disks technology

## Ultra SSD

supported VM types will be limited

Ultra SSD Disks come in several fixed sizes from 4 GiB up to 64 TiB and feature a flexible performance configuration model that allows you to independently configure IOPS and throughput.

Ultra SSDs support IOPS limits of 300 IOPS/GiB, up to a maximum of 160K IOPS per disk. To achieve the IOPS that you provisioned, ensure that the selected Disk IOPS is less than the VM IOPS.

With Ultra SSD Disks, the throughput limit of a single disk is 256 KiB/s for each provisioned IOPS, up to a maximum of 2000 MBps per disk (where MBps =  $10^6$  Bytes per second).

# Azure Ultra SSD

## Ultra SSD Managed Disk Offerings

<b>Disk size (GiB)</b>	4	8	16	32	64	128	256	512	1,024-65,536 (in increments of 1 TiB)
<b>IOPS range</b>	100-1,200	100-2,400	100-4,800	100-9,600	100-19,200	100-38,400	100-76,800	100-153,600	100-160,000
<b>Throughput Cap (MBps)</b>	300	600	1,200	2,000	2,000	2,000	2,000	2,000	2,000

# Planning High Availability

Availability Sets

Availability Zones

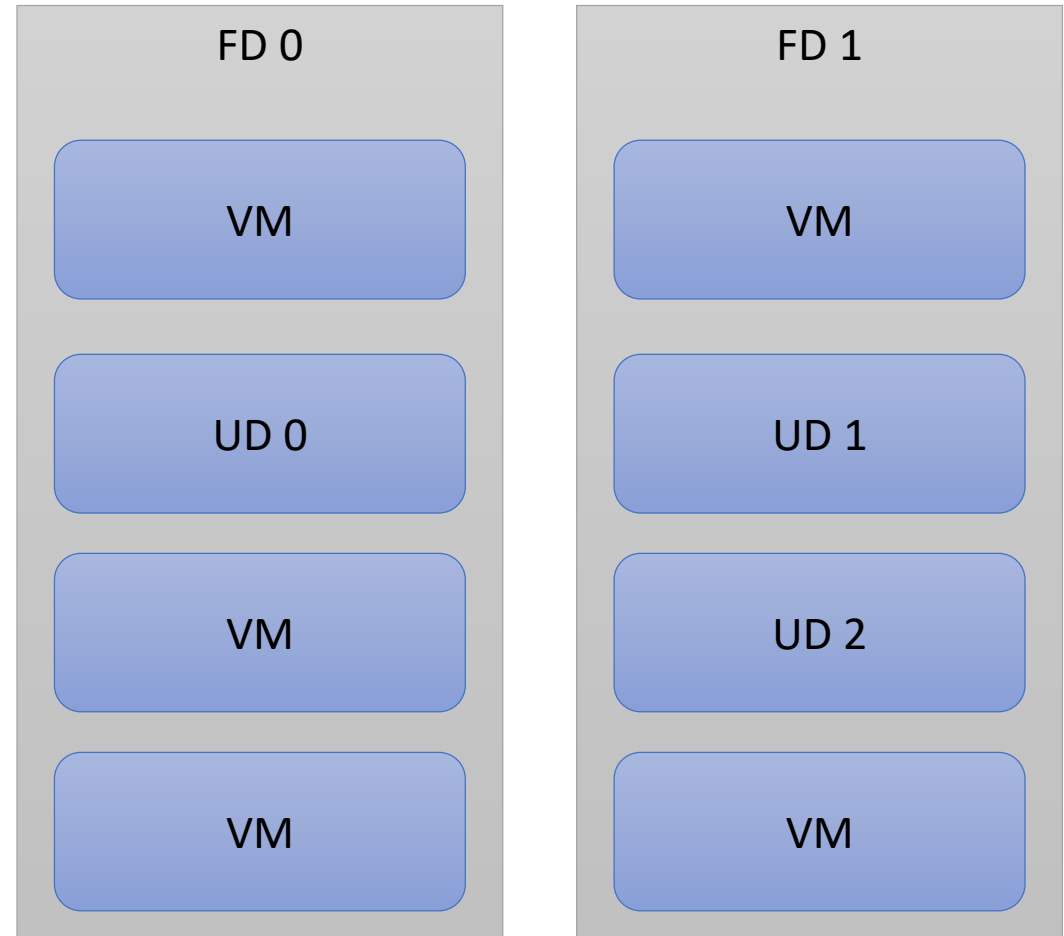

Region Pairs

Blast Radius

Feature	Capability / Provide
Availability Sets	High-availability <b>protection from hardware, network, and power failures in a DC</b>

# Terminology

<https://docs.microsoft.com/en-us/azure/active-directory/fundamentals/active-directory-what-is>

Azure subscription	Used to pay for Azure cloud services. You can have many subscriptions and they're linked to a credit card.
Azure tenant	A dedicated and trusted instance of Azure AD that's automatically created when your organization signs up for a Microsoft cloud service subscription, such as Microsoft Azure, Microsoft Intune, or Office 365. An Azure tenant represents a single organization.
Azure AD directory	Each Azure tenant has a dedicated and trusted Azure AD directory. The Azure AD directory includes the tenant's users, groups, and apps and is used to perform identity and access management functions for tenant resources.
Custom domain	Every new Azure AD directory comes with an initial domain name, domainname.onmicrosoft.com. In addition to that initial name, you can also add your organization's domain names, which include the names you use to do business and your users use to access your organization's resources, to the list. Adding custom domain names helps you to create user names that are familiar to your users, such as alain@contoso.com.

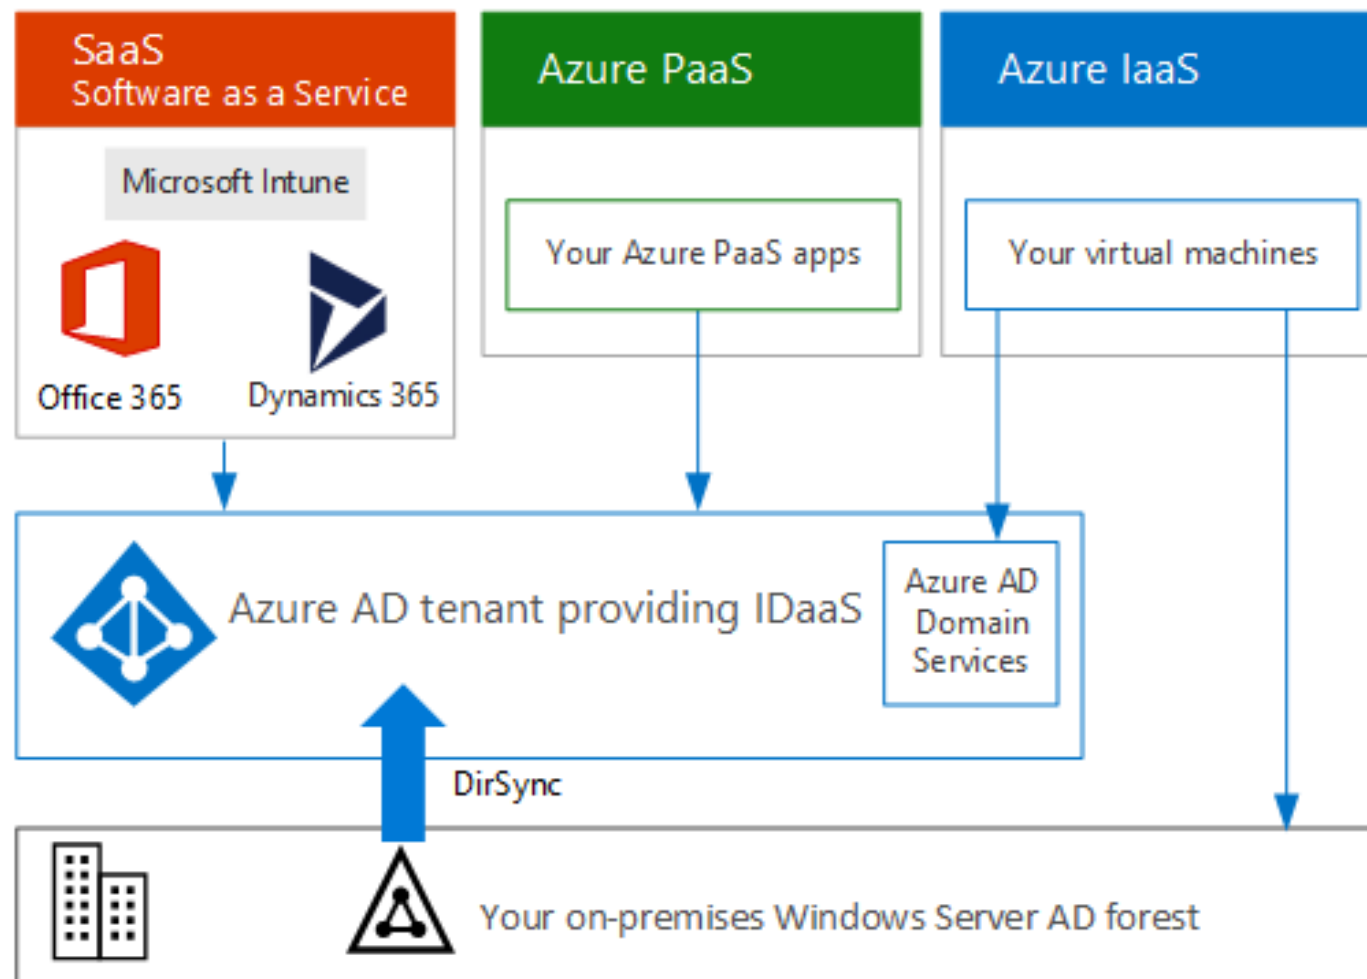

# Microsoft Identity

- <http://mystorageaccount.table.core.windows.net>
- <http://mystorageaccount.queue.core.windows.net>

# Storage HA Levels

- Locally redundant storage (LRS): Low-cost data redundancy for Azure Storage

Locally redundant storage (LRS) provides at least 99.999999999% (11 nines) durability of objects over a given year. LRS provides this object durability by replicating your data to a storage scale unit.

<https://docs.microsoft.com/en-us/azure/storage/common/storage-redundancy-lrs?toc=%2fazure%2fstorage%2fblobs%2ftoc.json>

# Storage HA Levels

- Zone-redundant storage (ZRS): Highly available Azure Storage applications

Zone-redundant storage (ZRS) replicates your data synchronously across three storage clusters in a single region. Each storage cluster is physically separated from the others and is located in its own availability zone (AZ).

<https://docs.microsoft.com/en-us/azure/storage/common/storage-redundancy-zrs?toc=%2fazure%2fstorage%2fblobs%2ftoc.json>

# Storage HA Levels

- Geo-redundant storage (GRS): Cross-regional replication for Azure Storage

Geo-redundant storage (GRS) is designed to provide at least 99.999999999999999% (16 9's) durability of objects over a given year by replicating your data to a secondary region that is hundreds of miles away from the primary region. If your storage account has GRS enabled, then your data is durable even in the case of a complete regional outage or a disaster in which the primary region isn't recoverable.

<https://docs.microsoft.com/en-us/azure/storage/common/storage-redundancy-grs?toc=%2fazure%2fstorage%2fblobs%2ftoc.json>

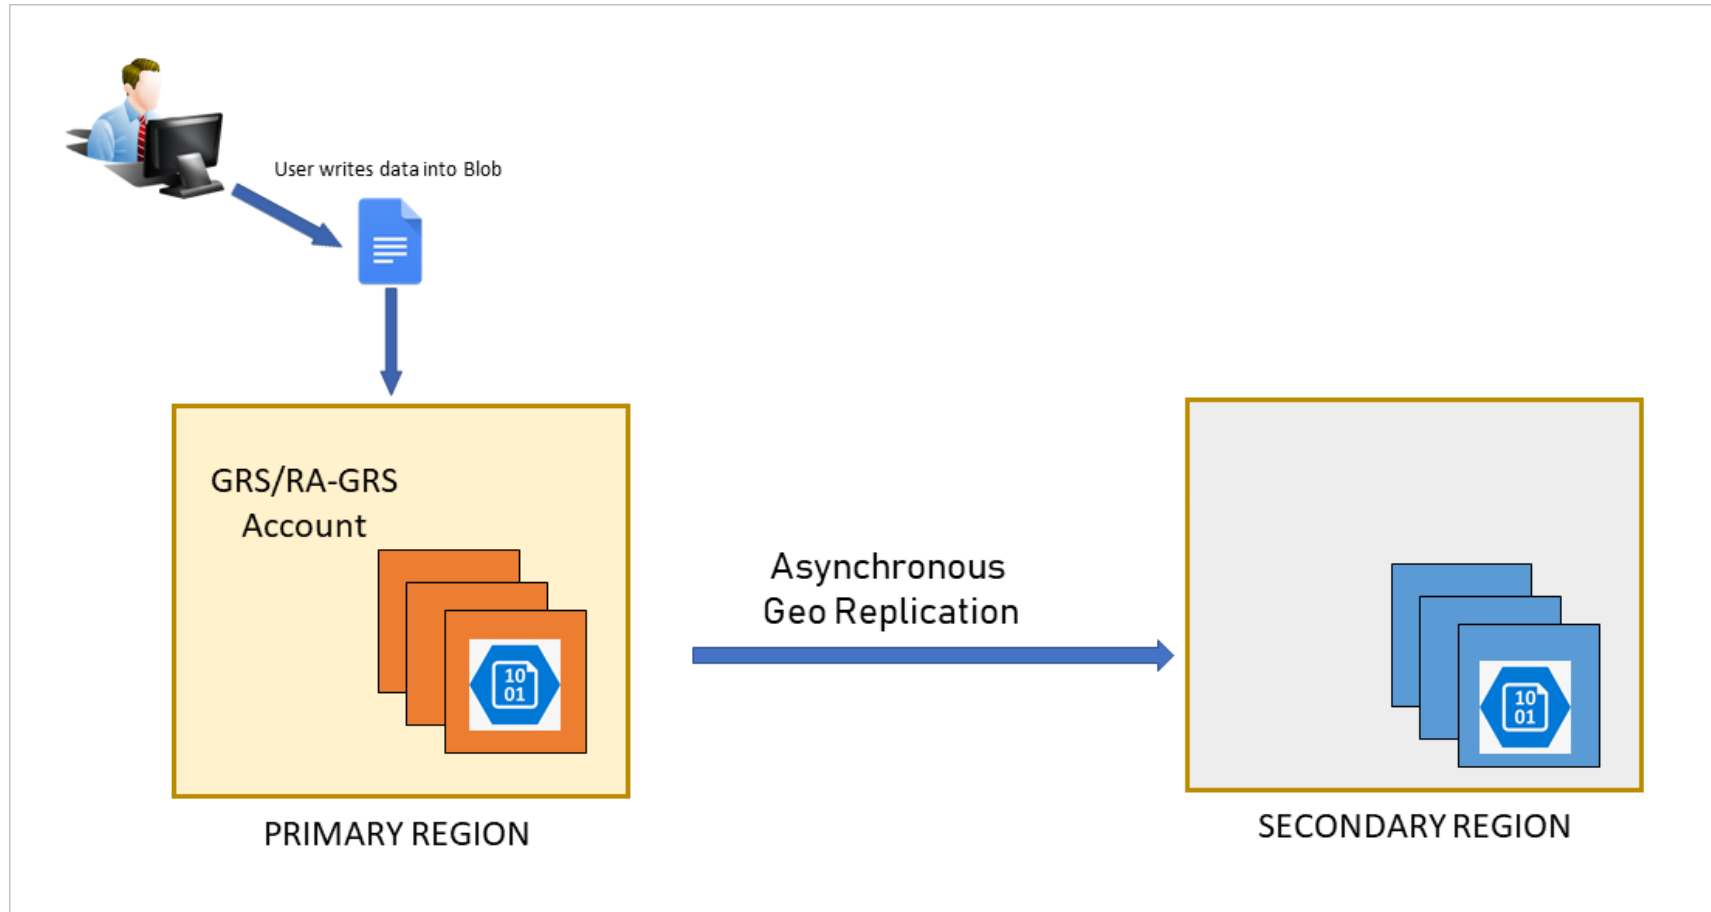

# Storage HA Levels

- Read-access geo-redundant storage (RA-GRS) is based on GRS. RA-GRS replicates your data to another data center in a secondary region, and also provides you with the option to read from the secondary region.

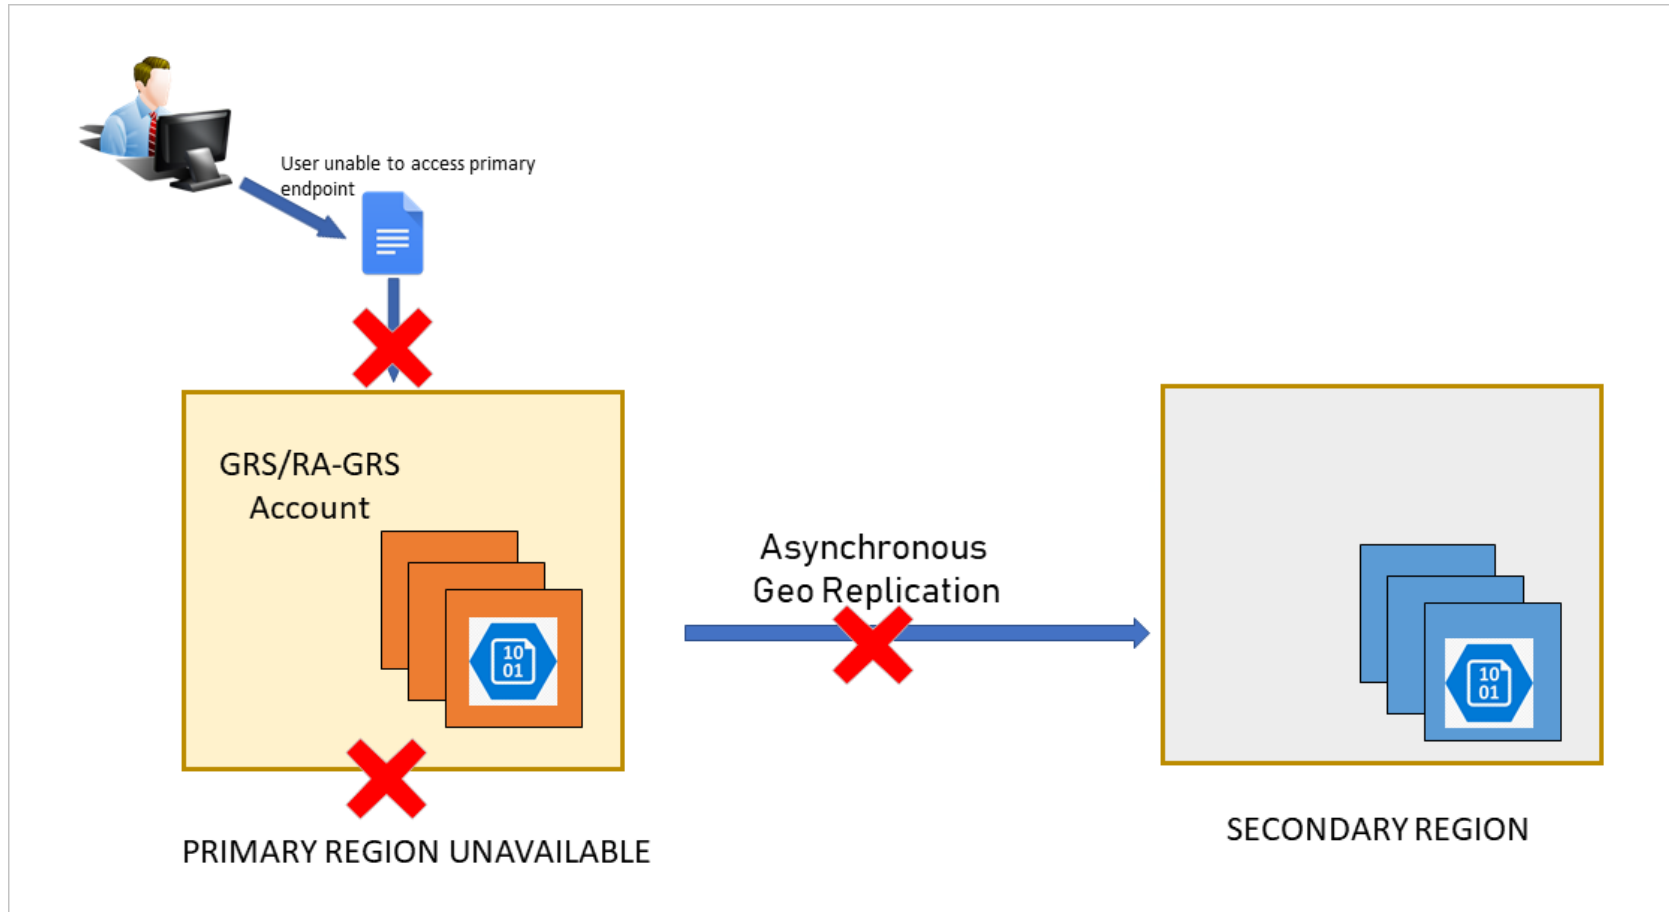

<https://docs.microsoft.com/en-us/azure/storage/common/storage-redundancy-grs?toc=%2fazure%2fstorage%2fblobs%2ftoc.json>

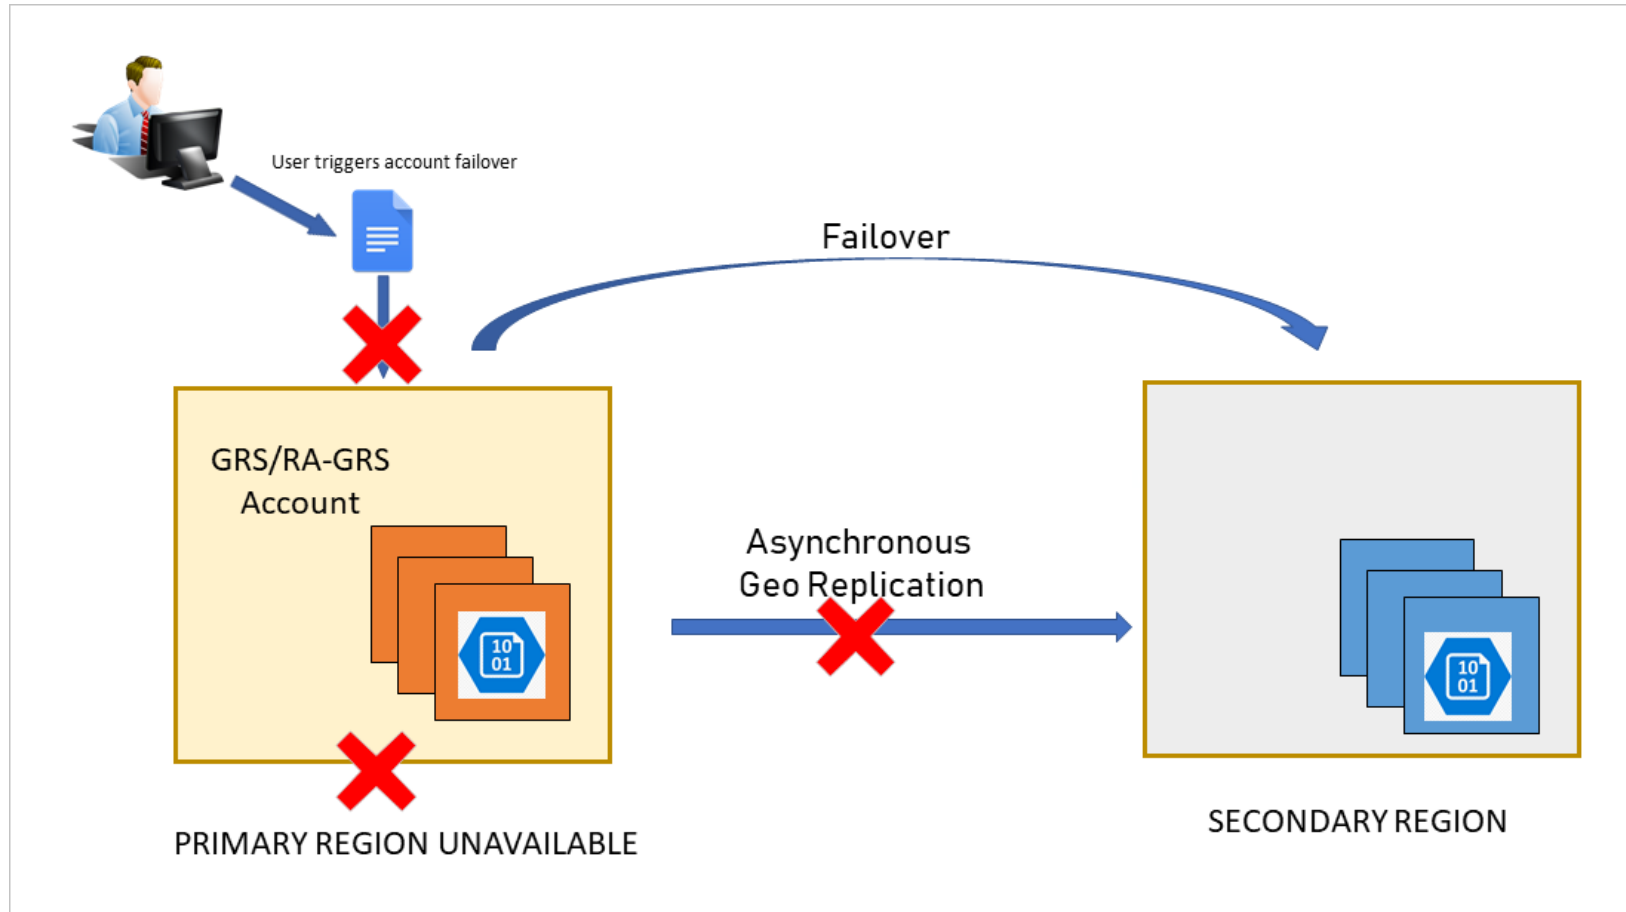

# Storage HA Process

# Storage HA Process

# Storage HA Process

# What is the RPO and RTO with GRS?

- The RPO indicates the point in time to which data can be recovered. Azure Storage typically has an RPO of less than 15 minutes, although there's currently no SLA on how long geo-replication takes.
- **Recovery Time Objective (RTO):** The RTO is a measure of how long it takes to perform the failover and get the storage account back online. The time to perform the failover includes the following actions:
  - The time until the customer initiates the failover of the storage account from the primary to the secondary region.
  - The time required by Azure to perform the failover by changing the primary DNS entries to point to the secondary location.

<https://docs.microsoft.com/en-us/azure/storage/common/storage-redundancy-grs?toc=%2fazure%2fstorage%2fblobs%2ftoc.json>

# Azure Storage Blob Service

- BLOB (Binary Large Object)
  - File, document, image, video, VM Disk, database etc.

<https://docs.microsoft.com/en-us/rest/api/storageservices/understanding-block-blobs--append-blobs--and-page-blobs>

# Blob Types

## Block Blob

- Block blobs are comprised of blocks
- Each of which is identified by a block ID
- Each block can be a different size, up to a maximum of 100 MB
- Block blob can include up to 50,000 blocks
- Insert, replace, delete blocks supported
- MAX 4.77 TB

## Append Blob

- is optimized for append operations
- blocks are added to the end of the blob only
- Updating or deleting of existing blocks is not supported
- append blob does not expose its block IDs.
- Each block in an append blob can be a different size, up to a maximum of 4 MB
- Ideal for logging, auditing
- MAX 195 GB

## Page Blob

- collection of 512-byte pages optimized for random read and write operations
- Azure virtual machine disks are backed by page blobs
- Azure offers two types of durable disk storage: premium and standard
- MAX 8TB

# Azure Storage Pricing

Data Storage (Capacity)

Data Operations

Blob Storage Lifecycle Management

# Soft Delete

- Enable you to save and recover your blob data in many cases where blob are deleted.

# Demo

Enable Soft Delete

# Demo

Static Web Sites in Storage Account

# Azure Storage Connection Options

- Azure Storage Explorer
- AzCopy Command line Utility
- Azure CLI
- Client Libraries (.net,java,python,php,node.js etc.)

# Authentication Options for Azure Blob Storage

- Storage Account Key
- Shared Access Signature
- RBAC with Azure Active Directory

# Shared Access Signature

- String containing a security token
- Can be appended to end of URL
- Access can be scoped to Container or Blob
- Specify permissions (read, write, delete, list)
- Validity Period start and end

# Stored Access Policy

- Group of permissions
- Shared Access Signature can reference policy
- Revoking Stored Access Policy also revokes all referencing SAS tokens

# Azure Active Directory RBAC

- Available for blob and Queue Services
- Users, Groups, Applications, Managed Service Identities
- Azure AD provide OAuth 2.0 Token
- Scope: Subscription, Resource Group, Storage Account, Blob Container
- Built-In role:
  - Storage Blob Data Contributor
  - Storage Blob Data Reader
- Https Only

Demo

Azure Storage Explorer

# AzCopy

- No limit to number of files in batch
- Pattern filters to select files
- Can continue batch after connection interruption
- Only copy newer/older files
- Modify file name and metadata during upload
- Throttle number of concurrent connections
- Generate log file
- SAS or Storage Account

# Azure CDN

Azure Champ

The background of the slide features a series of concentric, curved lines in a light gray color, creating a sense of motion or a globe-like effect. These lines are more prominent on the left side and fade out towards the right.

# Azure CDN

- Distributed network of Servers
- Provide data to users from closest source
- Offload traffic from origin servers to CND
- Typically static data

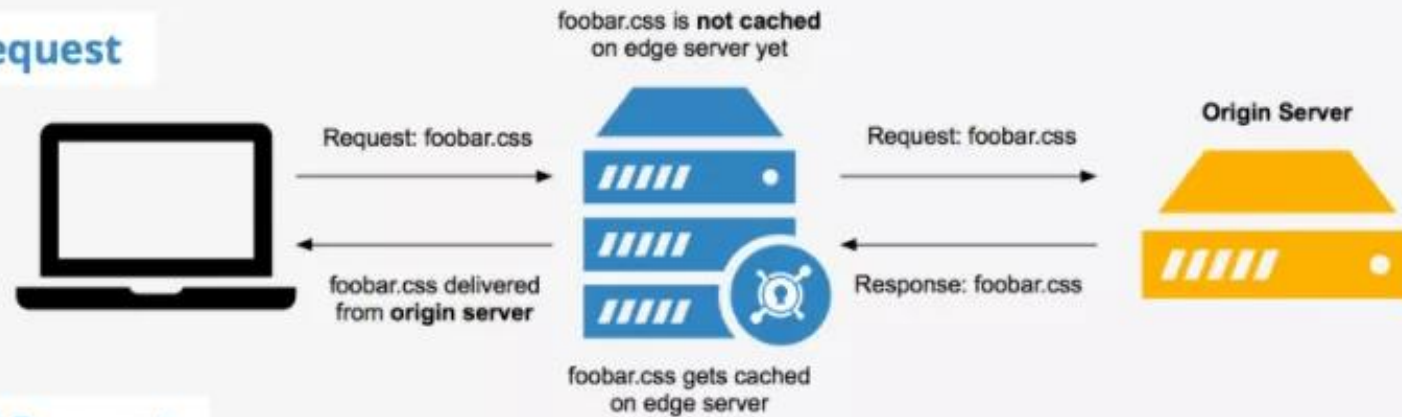

# Azure CDN

- Azure Storage blob service are 'origin server'
- Azure CDN servers are 'edge servers'

<https://docs.microsoft.com/en-us/azure/cdn/cdn-features>

# Azure CDN

## First Request

## Second Request

# Azure CDN Features

- HTTPS with Azure CDN Managed certificate
- Apply file compression to certain file types
- Large file download optimization
- Geo-filtering to restrict content by country

# Azure CDN Features

## Azure CDN Core Analytics

- Export to:
  - Blob Storage
  - Event Hubs
  - Log Analytics
- Metrics collected:
  - Number of request served from cache
  - Number of request retrieved from origin servers
  - GB of outbound data
  - HTTP status code returned to callers
  - Additional logging in Verizon Premium

Demo

Enabling Azure CDN

# Azure CDN Caching Behaviour

- Bypass cache: Do not cache and ignore origin-provided cache-directive headers.
- Override: Ignore origin-provided cache duration; use the provided cache duration instead. This will not override cache-control: no-cache.
- Set if missing: Honor origin-provided cache-directive headers, if they exist; otherwise, use the provided cache duration.

# Azure CDN caching behavior with query strings

- **Ignore query strings:** Default mode. In this mode, the CDN point-of-presence (POP) node passes the query strings from the requestor to the origin server on the first request and caches the asset. All subsequent requests for the asset that are served from the POP ignore the query strings until the cached asset expires.
- **Bypass caching for query strings:** In this mode, requests with query strings are not cached at the CDN POP node. The POP node retrieves the asset directly from the origin server and passes it to the requestor with each request.
- **Cache every unique URL:** In this mode, each request with a unique URL, including the query string, is treated as a unique asset with its own cache. For example, the response from the origin server for a request for `example.ashx?q=test1` is cached at the POP node and returned for subsequent caches with the same query string. A request for `example.ashx?q=test2` is cached as a separate asset with its own time-to-live setting.

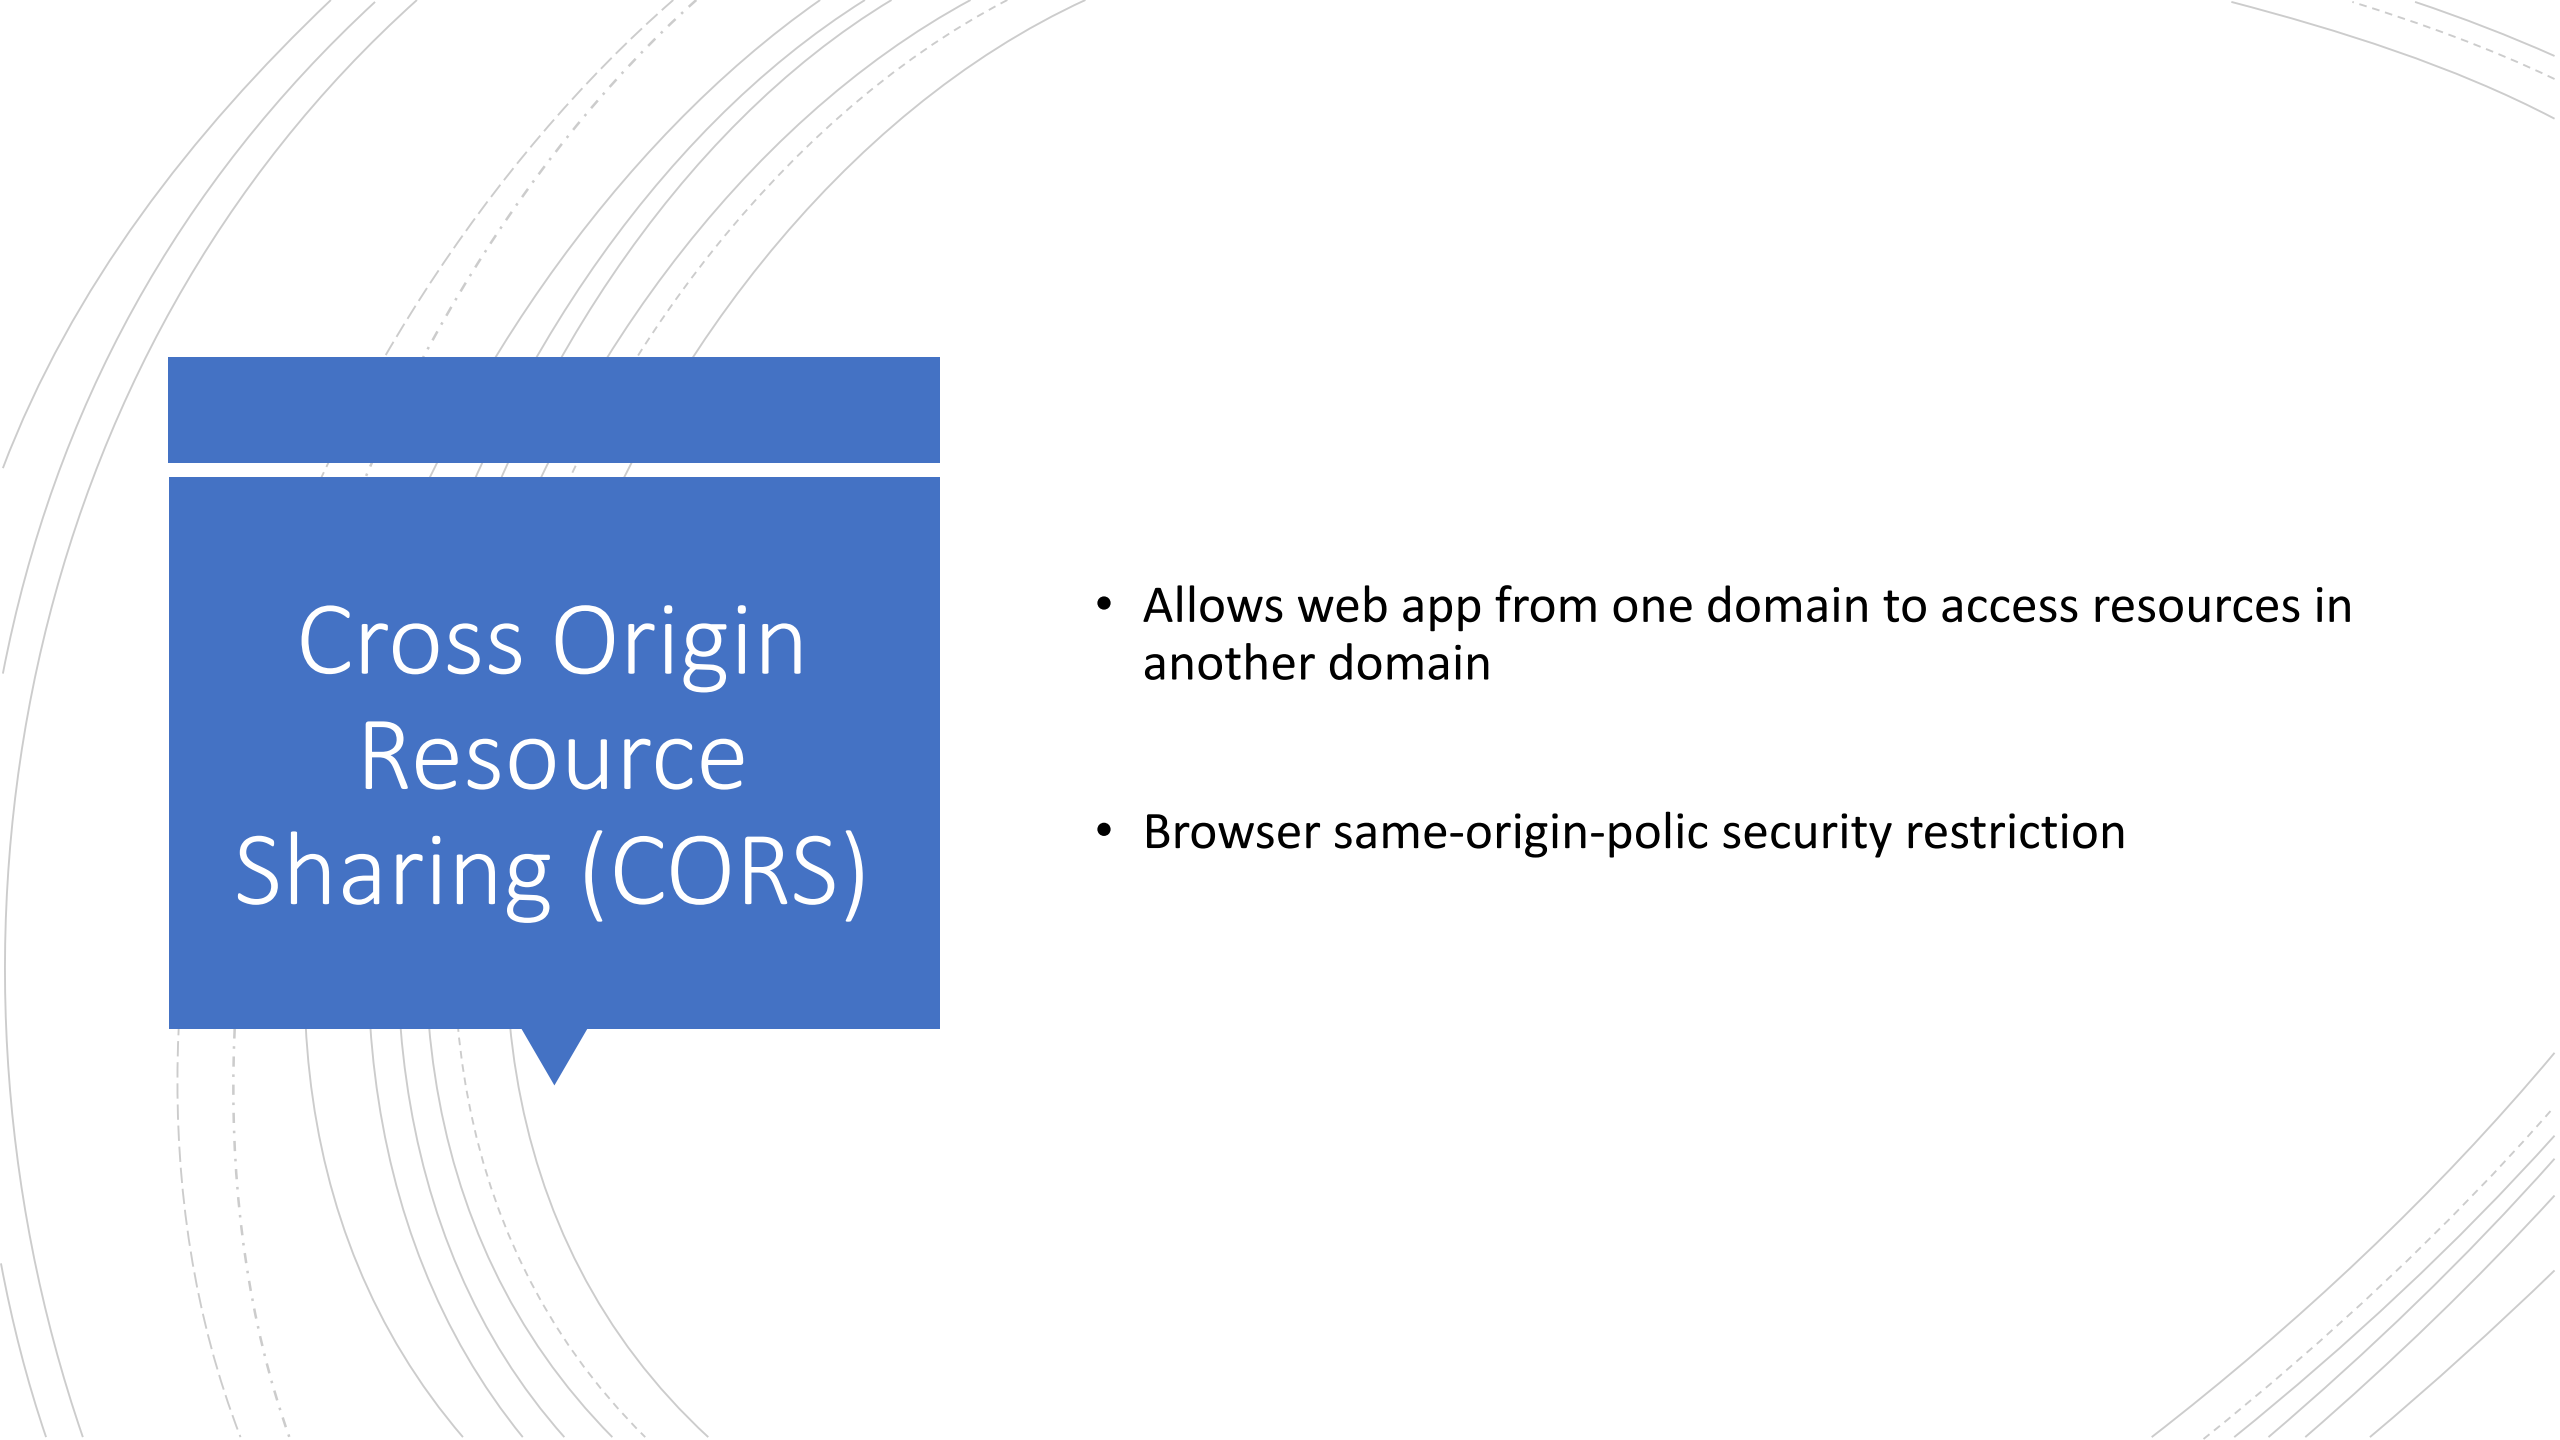

<https://docs.microsoft.com/en-us/azure/cdn/cdn-query-string>

# Azure CDN SSL Certificates

- Mixed content warnings
- HTTPS on custom domain
  - Azure CDN can provision and manage certificate (Verizon, Akamai)
  - Import your own certificate (Microsoft Standard pricing tier only)

The background of the slide features a series of thin, curved lines in shades of gray, creating a sense of motion and depth. These lines are more prominent on the left side and fade towards the right.

## Cross Origin Resource Sharing (CORS)

- Allows web app from one domain to access resources in another domain
- Browser same-origin-policy security restriction

# Azure Virtual Networks

Azure Champ

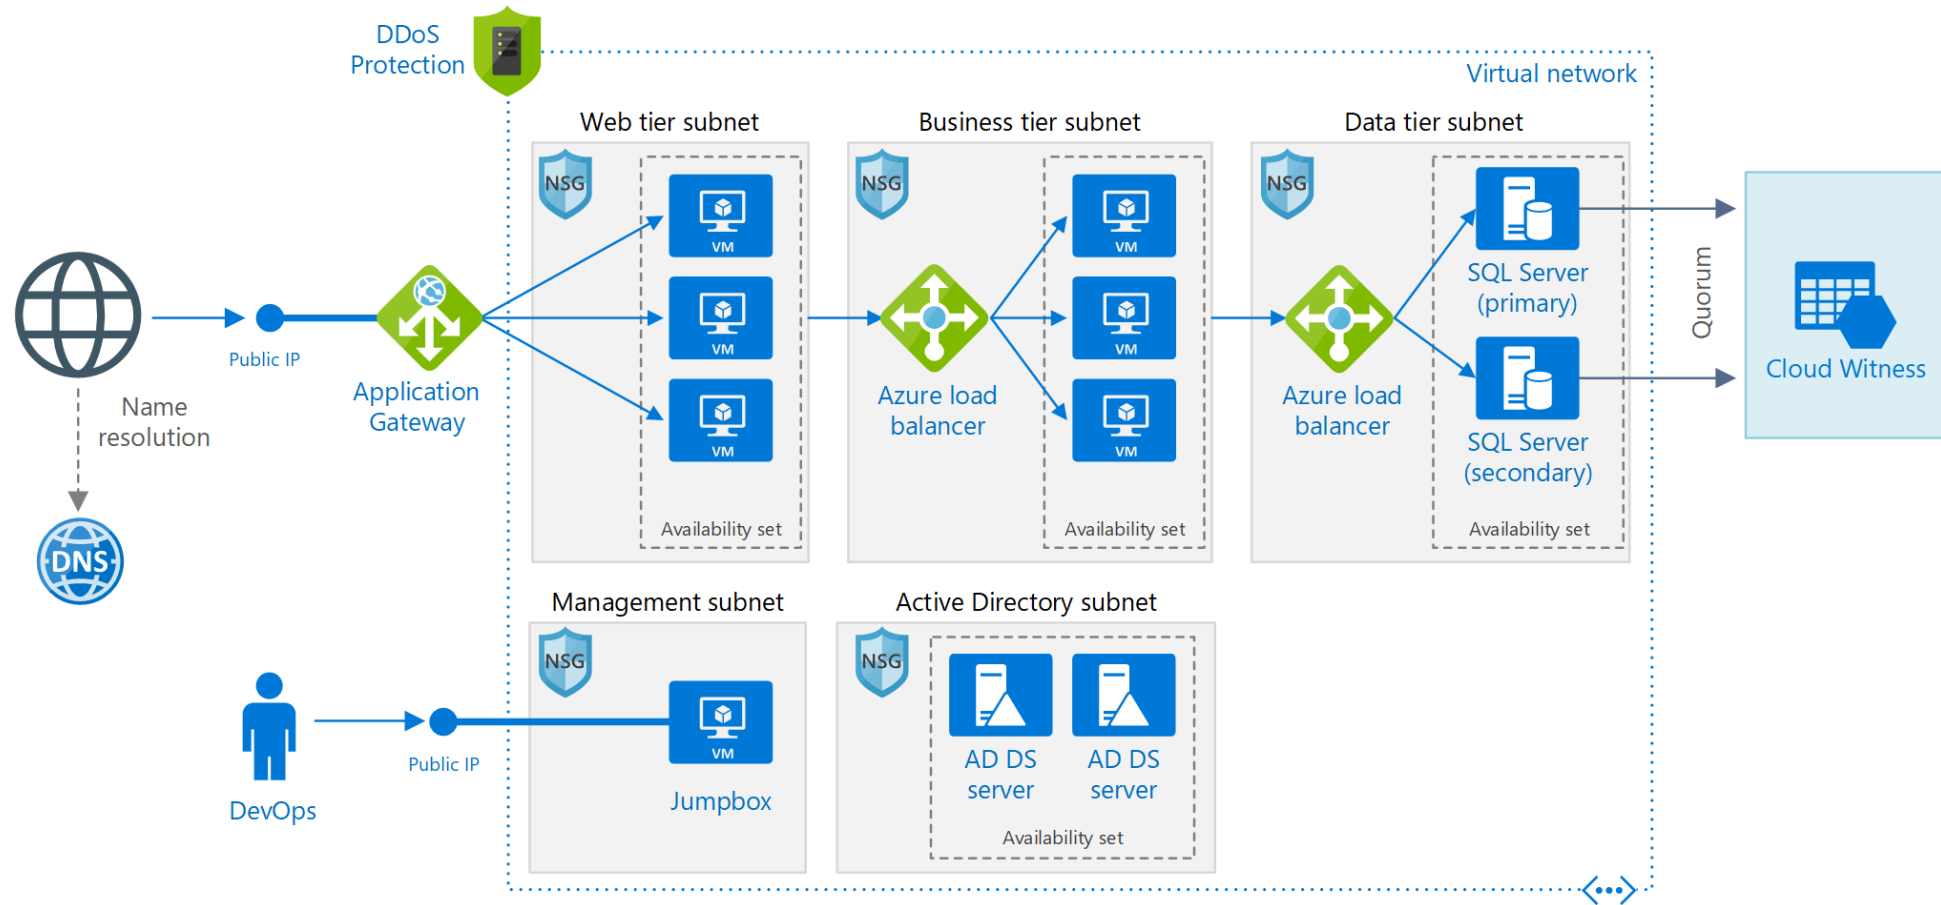

# The Azure Virtual Network

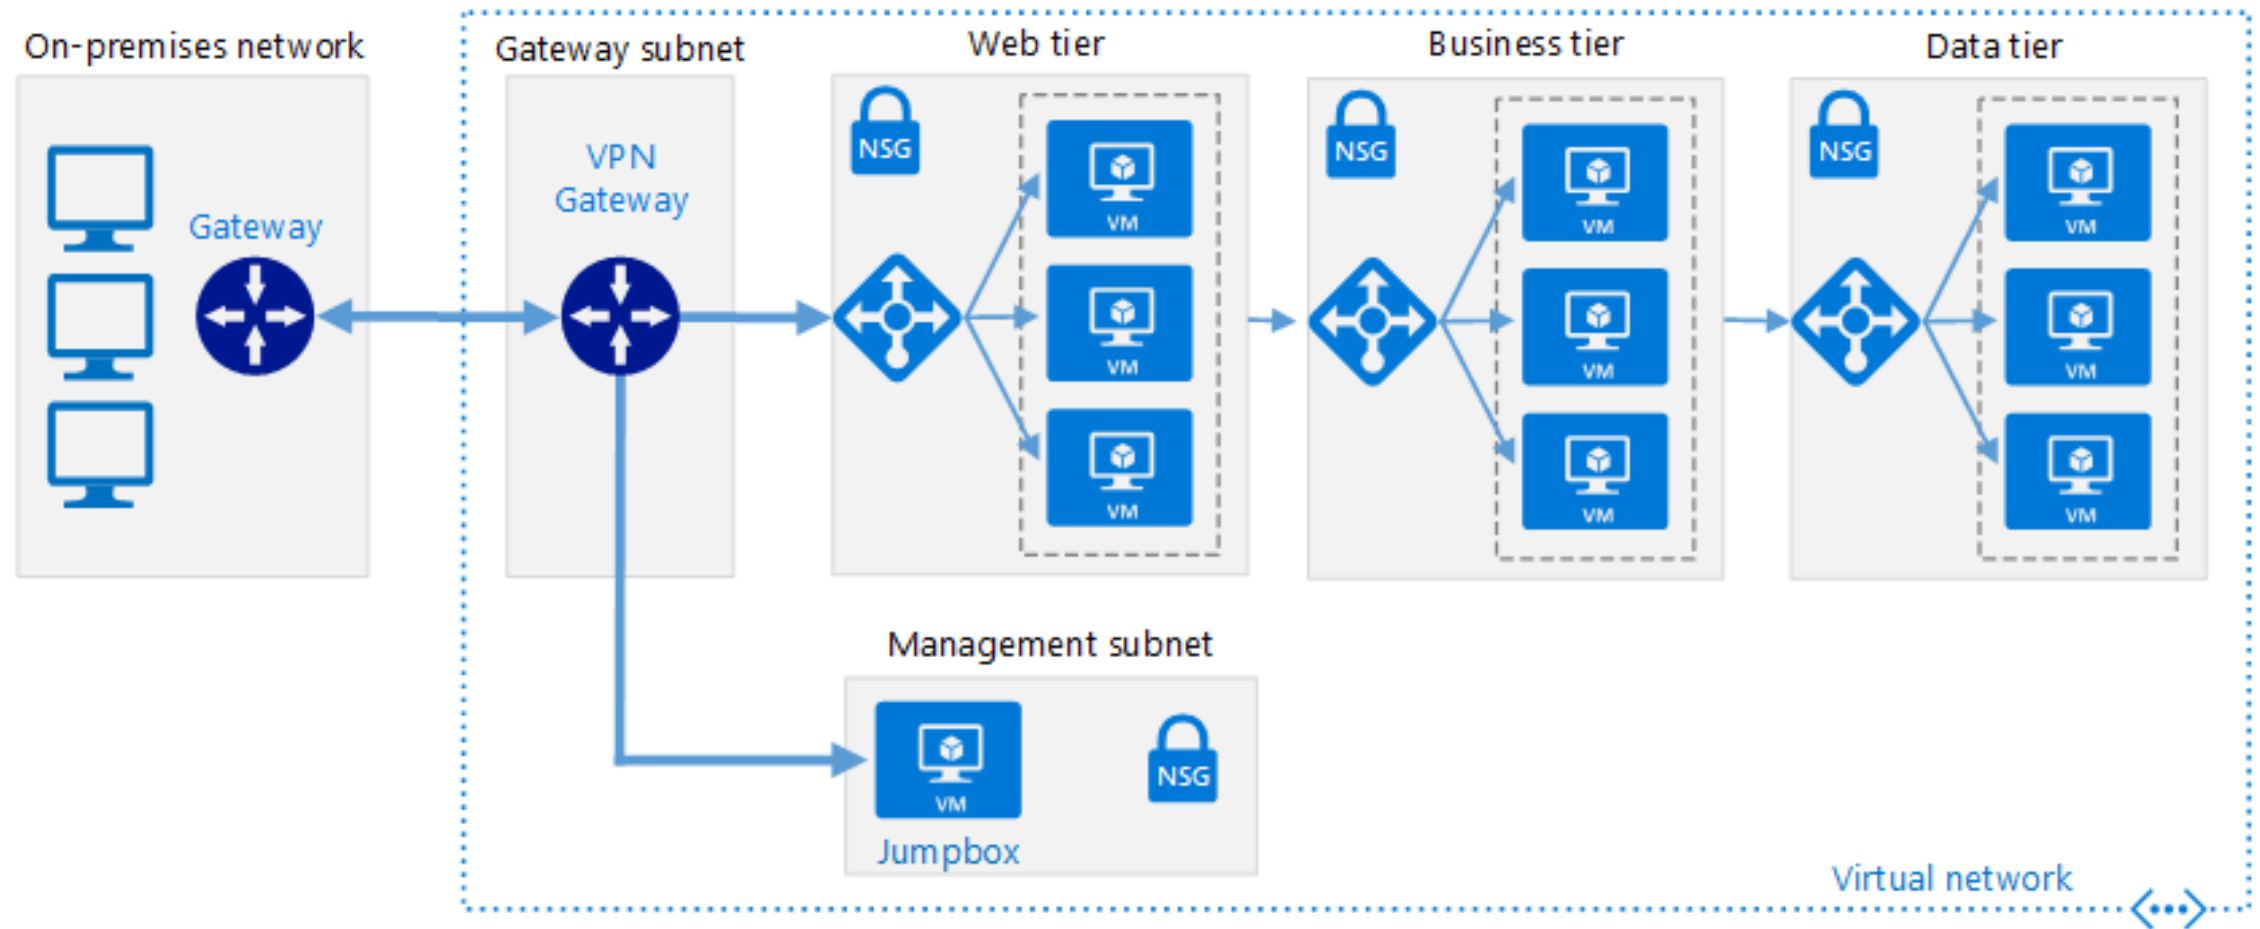

Azure Virtual Network enables many types of Azure resources, such as Azure Virtual Machines (VM), to securely communicate with each other, the internet, and on-premises networks.

- Isolation and segmentation
- Communicate with the internet
- Communicate between Azure resources
- Communicate with on-premises resources
- Filter network traffic
- Route network traffic

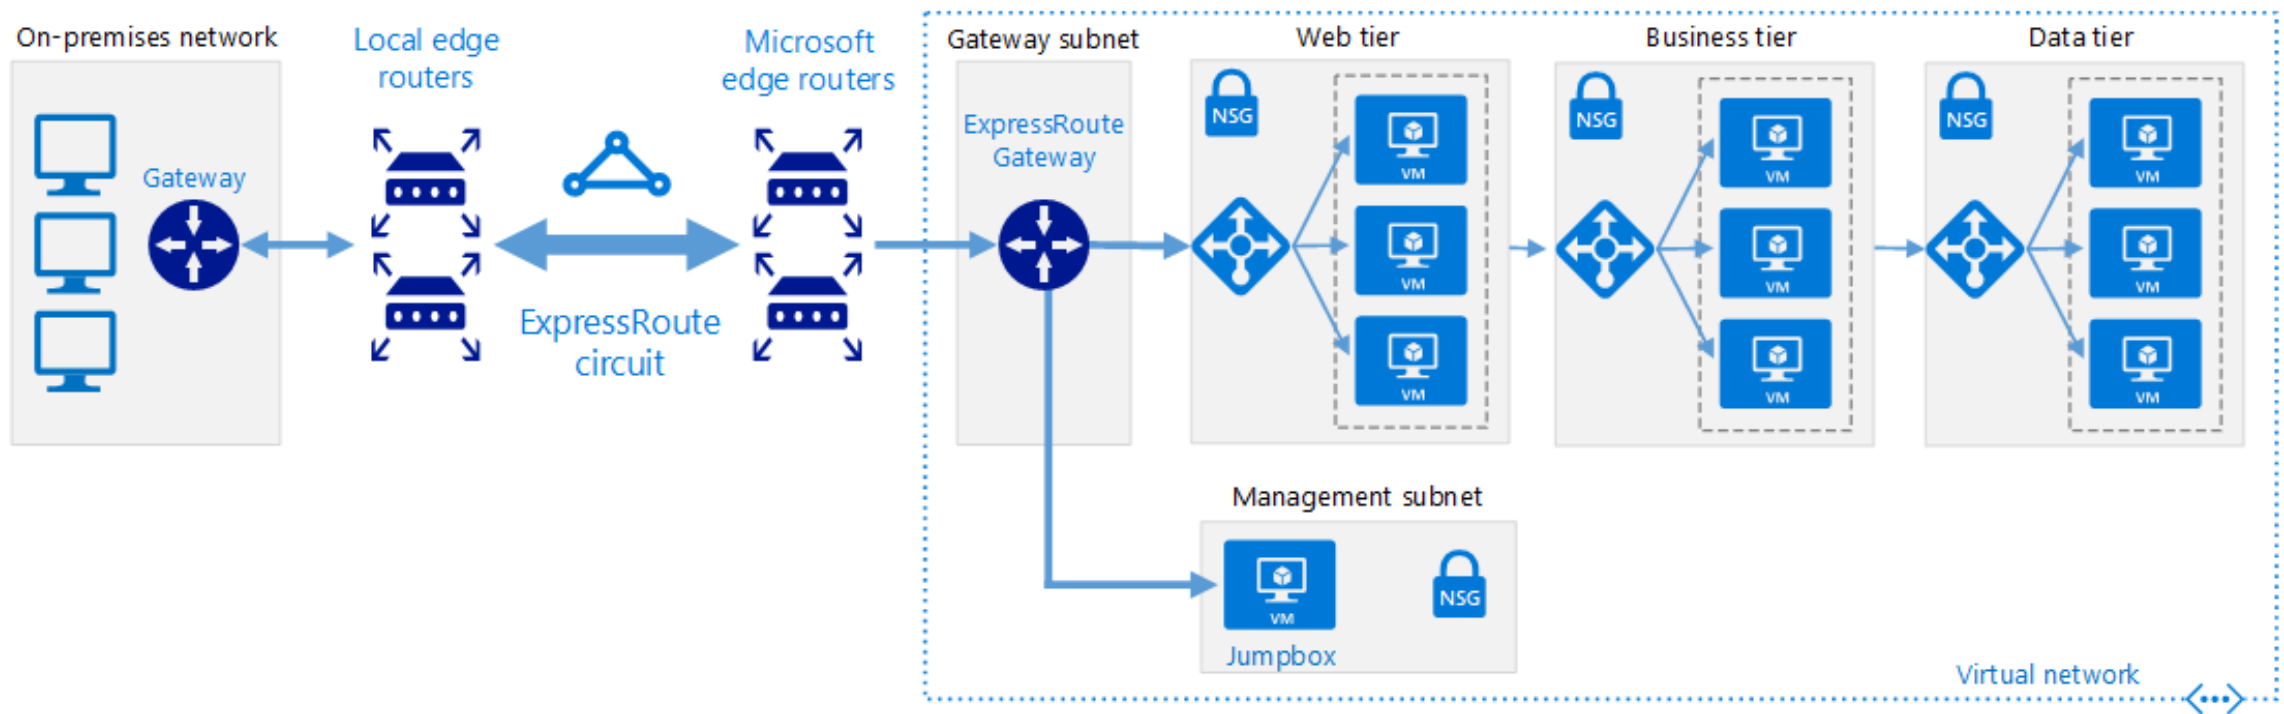

# The Azure Virtual Network

# The Azure Virtual Network

# The Azure Virtual Network

# Name Resolution for Azure vNets

- Azure-provided name resolution
- Azure DNS

# Azure- provided name resolution

- No configuration required
- All VMs within a VNet can resolve each others' host names
- Problem: cross-VNet name resolution
- Problem: No custom DNS suffix
- You can add custom DNS server IP addresses
- You can host your own DNS server(s)

# Azure DNS

- Host your public DNS domain in Azure
  - Use Azure geo-distributed name servers
- Create private DNS zones
  - Linked to Vnets
  - Registration Vnet
  - Resolution VNet

# Azure Network Design Practices

- Design Virtual Networks
- Design IP Addressing
- Design Subnets

<https://docs.microsoft.com/en-us/azure/migrate/migrate-best-practices-networking>

# Design virtual networks

- Azure resources communicate privately, directly, and securely with each other over VNets.
- You can configure endpoint connections on VNets for VMs and services that require internet communication.
- A VNet is a logical isolation of the Azure cloud that's dedicated to your subscription.
- You can implement multiple VNets within each Azure subscription and Azure region.
- Each VNet is isolated from other VNets.
- VNets can contain private and public IP addresses defined in RFC 1918, expressed in CIDR notation. Public IP addresses are not directly accessible from the internet.
- VNets can connect to each other using VNet peering. Connected VNets can be in the same or different regions. Thus resources in one VNet can connect to resources in other VNets.
- By default, Azure routes traffic between subnets within a VNet, connected VNets, on-premises networks, and the internet.

# Plan IP addressing

- You should assign an address space that isn't larger than a CIDR range of /16 for each VNet. VNets allow for the use of 65536 IP addresses, and assigning a smaller prefix than /16 would result in the loss of IP addresses. It's important not to waste IP addresses, even if they're in the private ranges defined by RFC 1918.
- The VNet address space shouldn't overlap with on-premises network ranges.
- Network Address Translation (NAT) shouldn't be used.
- Overlapping addresses can cause networks that can't be connected and routing that doesn't work properly. If networks overlap, you'll need to redesign the network or use network address translation (NAT).

# Design subnets

- You can create multiple subnets within each VNet.
- By default, Azure routes network traffic between all subnets in a VNet.
- Your subnet decisions are based on your technical and organizational requirements.
- You create subnets using CIDR notation.
- When deciding on network range for subnets, it's important to note that Azure retains five IP addresses from each subnet that can't be used. For example, if you create the smallest available subnet of /29 (with eight IP addresses), Azure will retain **five addresses**, so you only have three usable addresses that can be assigned to hosts on the subnet.
- In most cases, using /28 as the smallest subnet is recommended.

Demo

Create Virtual Network

# Network Security Groups(NSGs)

- Statefull firewall for inbound and outbound traffic
- 5 tuple hash source,destination IP and ports, protocol
- Has default rules
- Augmented rules
- Services tags and ASGs
- Bound to vNIC or Subnet

# Service Tags

- A service tag represents a group of IP address prefixes to help minimize complexity for security rule creation.
- You cannot create your own service tag, nor specify which IP addresses are included within a tag.
- Microsoft manages the address prefixes encompassed by the service tag, and automatically updates the service tag as addresses change.
- You can use service tags in place of specific IP addresses when creating security rules.

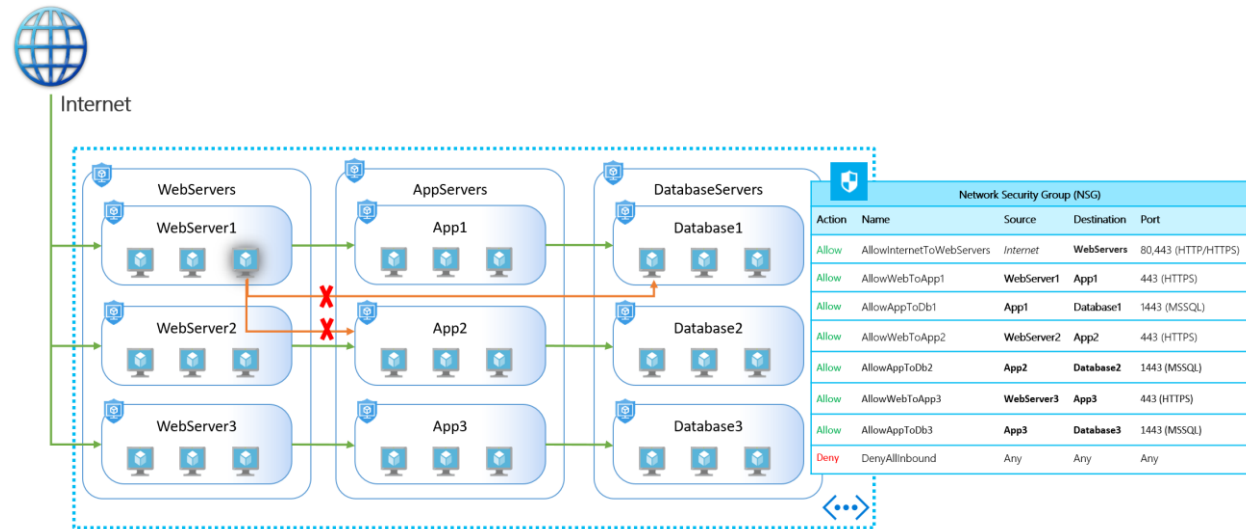

# Service Tags

- Virtual Networks
- Azure Load Balancer
- Internet
- Azure Cloud
- Azure Storage
- Azure Traffic Manager
- Etc .....

<https://docs.microsoft.com/en-us/azure/virtual-network/security-overview#service-tags>

# Application Security Groups (ASGs)

- Application security groups enable you to configure network security as a natural extension of an application's structure, allowing you to group virtual machines and define network security policies based on those groups.

Custom Routing

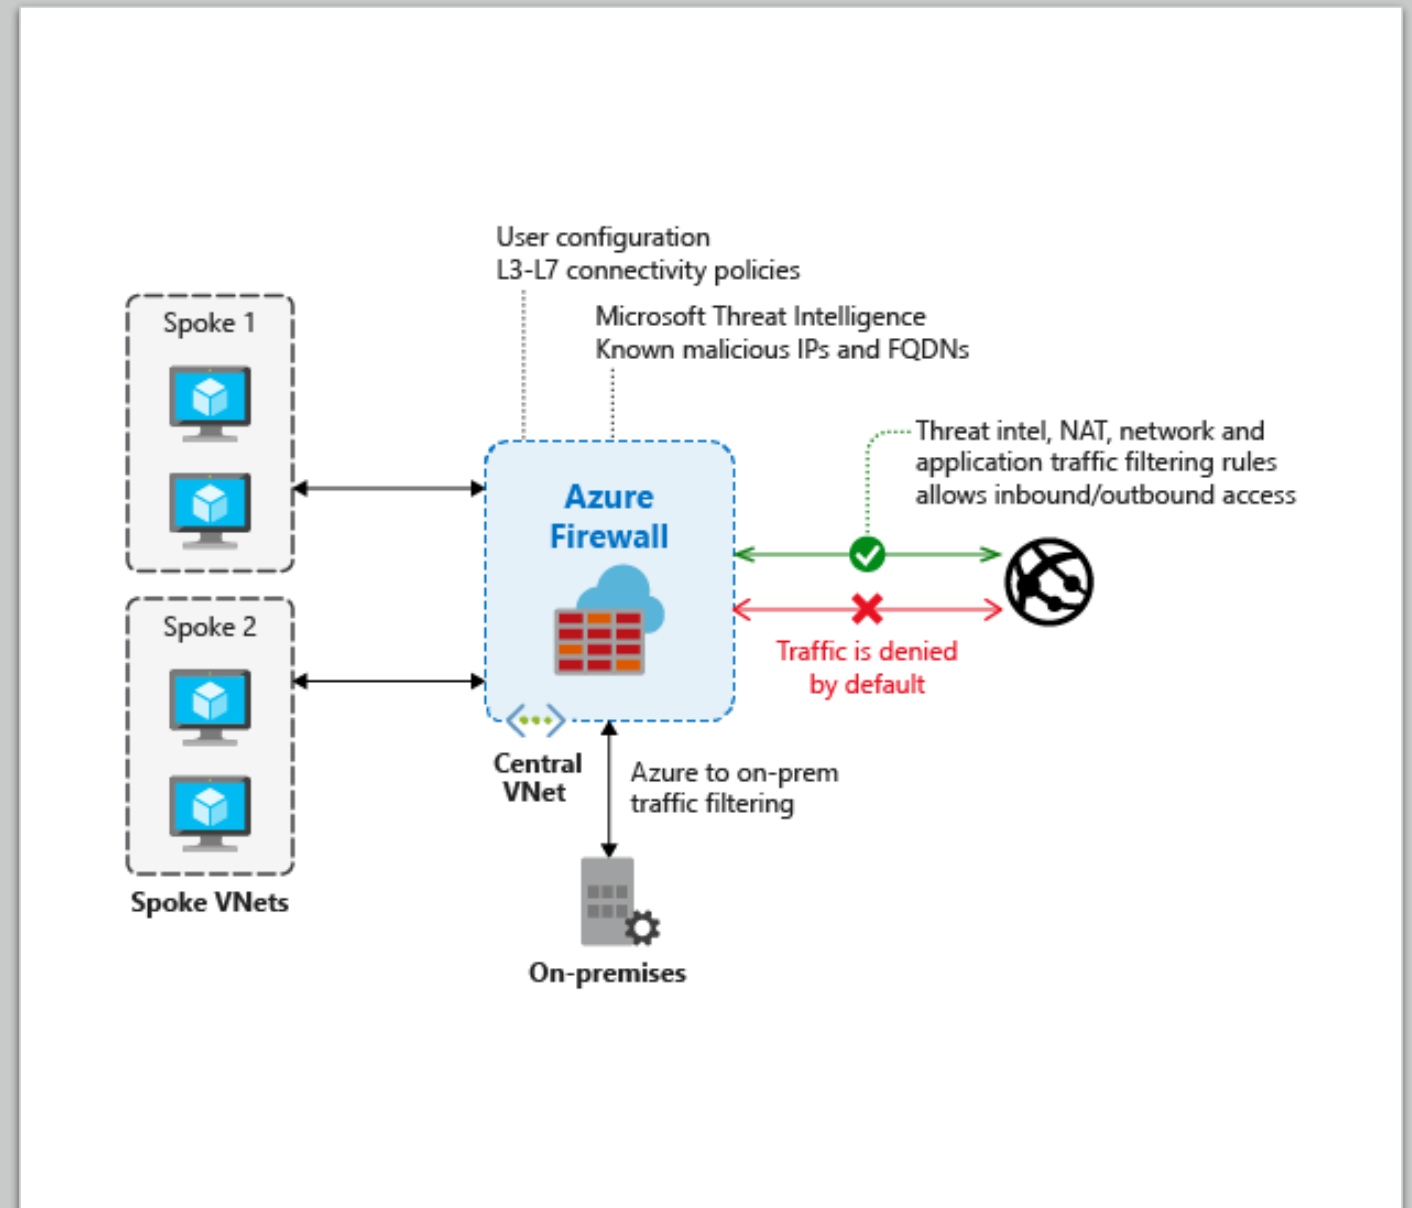

# Azure Firewall

Azure Firewall is a managed, cloud-based network security service that protects your Azure Virtual Network resources.

It is a fully stateful firewall as a service with built-in high availability and unrestricted cloud scalability.

# Azure Firewall

- Built-in high availability
- Unrestricted cloud scalability
- Application FQDN filtering rules
- Network traffic filtering rules
- FQDN tags
- Service tags
- Threat intelligence
- Outbound SNAT support
- Inbound DNAT support
- Azure Monitor logging

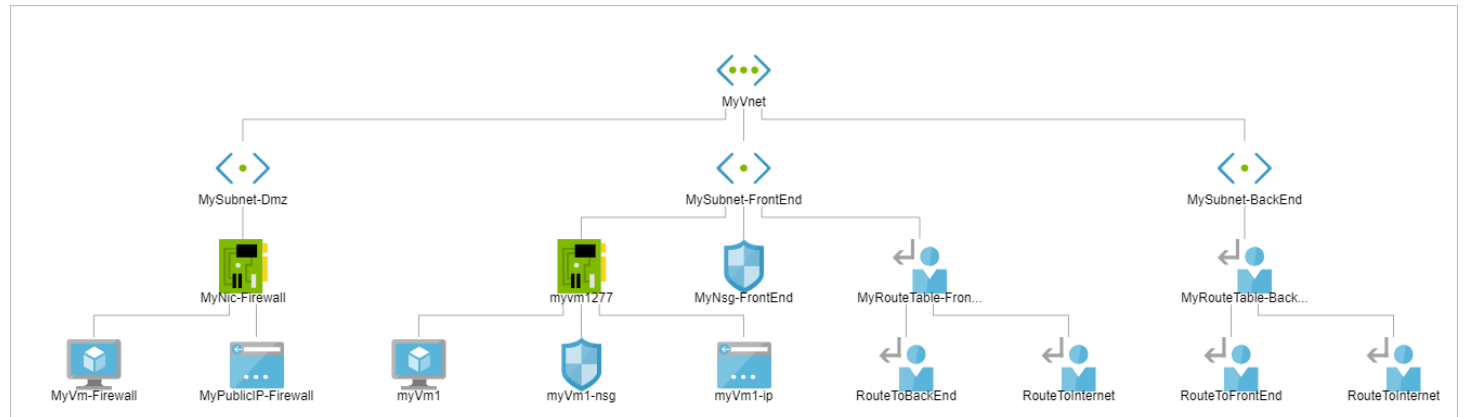

Demo

Azure Firewall

# Azure Network Watcher

- Azure Network Watcher provides tools to monitor, diagnose, view metrics, and enable or disable logs for resources in an Azure virtual network.
- View resources in a virtual network and their relationships

# Azure Network Watcher

- Diagnose network traffic filtering problems to or from a VM
- Diagnose network routing problems from a VM
- Diagnose outbound connections from a VM
- Capture packets to and from a VM
- Diagnose problems with an Azure Virtual network gateway and connections
- Determine relative latencies between Azure regions and internet service providers
- View security rules for a network interface

Azure Network Watcher

# Azure DNS

Azure Champ

# Azure-provided name resolution

- No configuration required
- All VMs within a VNet can resolve each others' host names
- Problem: cross-VNet name resolution
- Problem: No custom DNS suffix
- You can add custom DNS server IP addresses
- You can host your own DNS server(s)

The background of the slide features a series of thin, curved lines in shades of gray, creating a sense of motion and depth. These lines are more prominent on the left side and fade towards the right.

# Azure DNS

- Host your public DNS domain in Azure
  - Use Azure geo-distributed name servers
- Create private DNS zones
  - Linked to Vnets
  - Registration Vnet
  - Resolution VNet

The background of the slide features a series of concentric, curved lines in a light gray color, creating a sense of motion or a stylized globe. These lines are more prominent on the left side and fade out towards the right.

# The Resolution Virtual Networks

- To publish a private DNS zone to your virtual network, you specify the list of virtual networks that are allowed to resolve records within the zone. These are called resolution virtual networks.

The background of the slide features a series of concentric, curved lines in a light gray color, creating a sense of motion or a stylized globe. These lines are more prominent on the left side and fade towards the right.

# The Registration Virtual Network

- You may also specify a virtual network for which Azure DNS maintains hostname records whenever a VM is created, changes IP, or is deleted. This is called a registration virtual network.

# Azure Private DNS Zones Benefit

- Removes the need for custom DNS solutions. Previously, many customers created custom DNS solutions to manage DNS zones in their virtual network. You can now perform DNS zone management by using the native Azure infrastructure, which removes the burden of creating and managing custom DNS solutions.
- Use all common DNS records types. Azure DNS supports A, AAAA, CNAME, MX, PTR, SOA, SRV, and TXT records.
- Automatic hostname record management. Along with hosting your custom DNS records, Azure automatically maintains hostname records for the VMs in the specified virtual networks. In this scenario, you can optimize the domain names you use without needing to create custom DNS solutions or modify applications.
- Hostname resolution between virtual networks. Unlike Azure-provided host names, private DNS zones can be shared between virtual networks. This capability simplifies cross-network and service-discovery scenarios, such as virtual network peering.
- Familiar tools and user experience. To reduce the learning curve, this new offering uses well-established Azure DNS tools (PowerShell, Azure Resource Manager templates, and the REST API).
- Split-horizon DNS support. With Azure DNS, you can create zones with the same name that resolve to different answers from within a virtual network and from the public internet. A typical scenario for split-horizon DNS is to provide a dedicated version of a service for use inside your virtual network.
- Available in all Azure regions. The Azure DNS private zones feature is available in all Azure regions in the Azure public cloud.

# Azure Private DNS Zones Limitations

- Only one registration virtual network is allowed per private zone.
- Up to 10 resolution virtual networks are allowed per private zone. This limit will be removed when this feature is generally available.
- A specific virtual network can be linked to only one private zone as a registration virtual network.
- A specific virtual network can be linked to up to 10 private zones as a resolution virtual network. This limit will be removed when this feature is generally available.
- If you specify a registration virtual network, the DNS records for the VMs from that virtual network that are registered to the private zone are not viewable or retrievable from the Azure Powershell and Azure CLI APIs. The VM records are indeed registered and will resolve successfully.
- Reverse DNS works only for private IP space in the registration virtual network.
- Reverse DNS for a private IP that isn't registered in the private zone (for example, a private IP for a virtual machine in a virtual network that is linked as a resolution virtual network to a private zone) returns `internal.cloudapp.net` as the DNS suffix. However, this suffix isn't resolvable.
- The virtual network must be completely empty the first time you link it to a private zone as a registration or resolution virtual network. However, the virtual network can then be non-empty for future linking as a registration or resolution virtual network, to other private zones.
- Currently, conditional forwarding is not supported (for example, for enabling resolution between Azure and OnPrem networks). For information about how customers can realize this scenario via other mechanisms, see [Name resolution for VMs and role instances](#).

# Azure DNS Private Zones Inter vNET Resolution

# Azure Load Balancing

Azure Champ

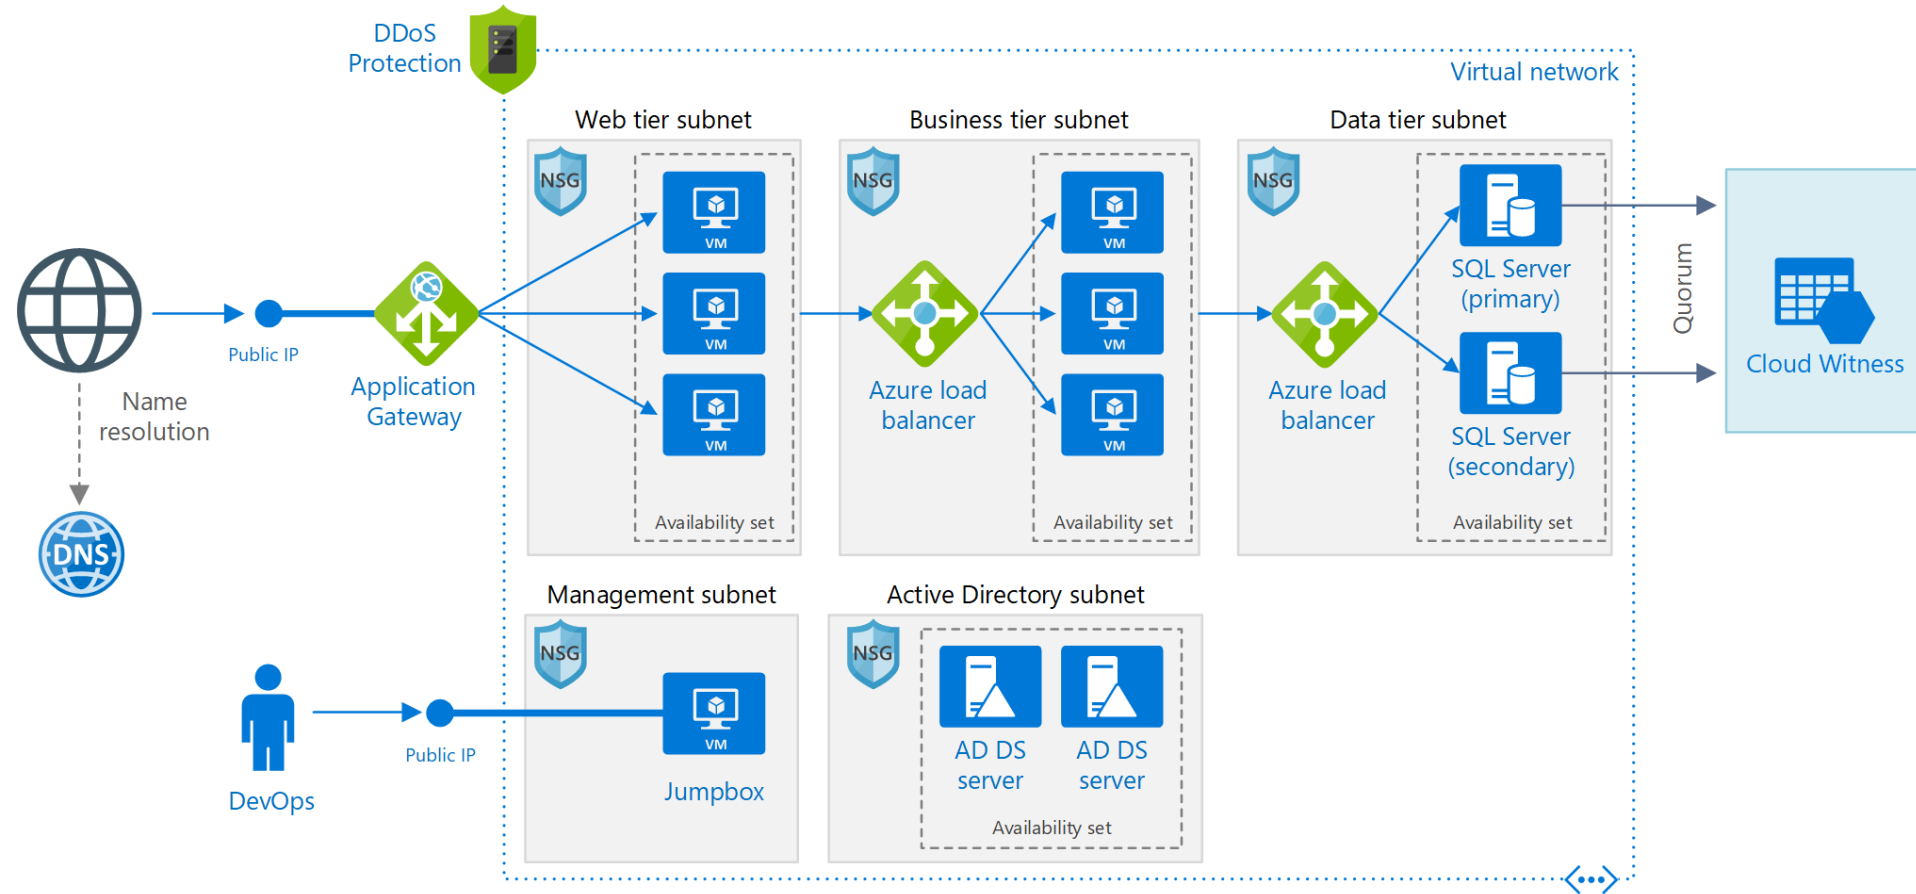

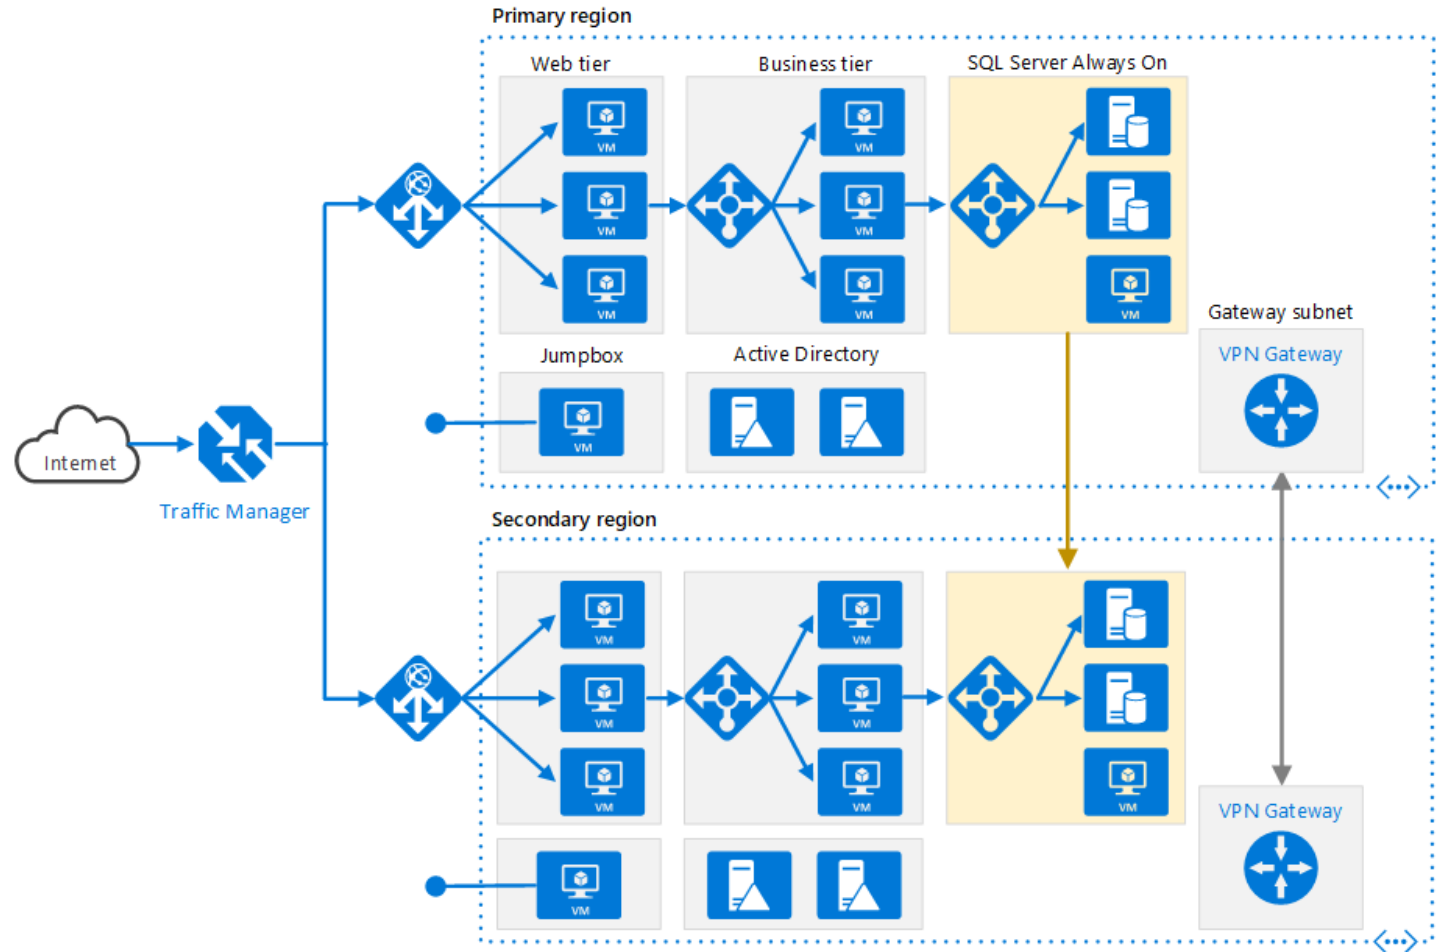

# Load Balancing in Azure

Load Balancer	Application Gateway	Traffic Manager
OSI Layer 4 (TCP, UDP)	OSI Layer 7	OSI Layer 7
5-tuple Hash	SSL Offload	Global DNS Load Balancing
Load Distribution	Web Application Firewall	
Network Address Translation (NAT)		

# Load Balancing in Azure

# Load Balancing in Azure

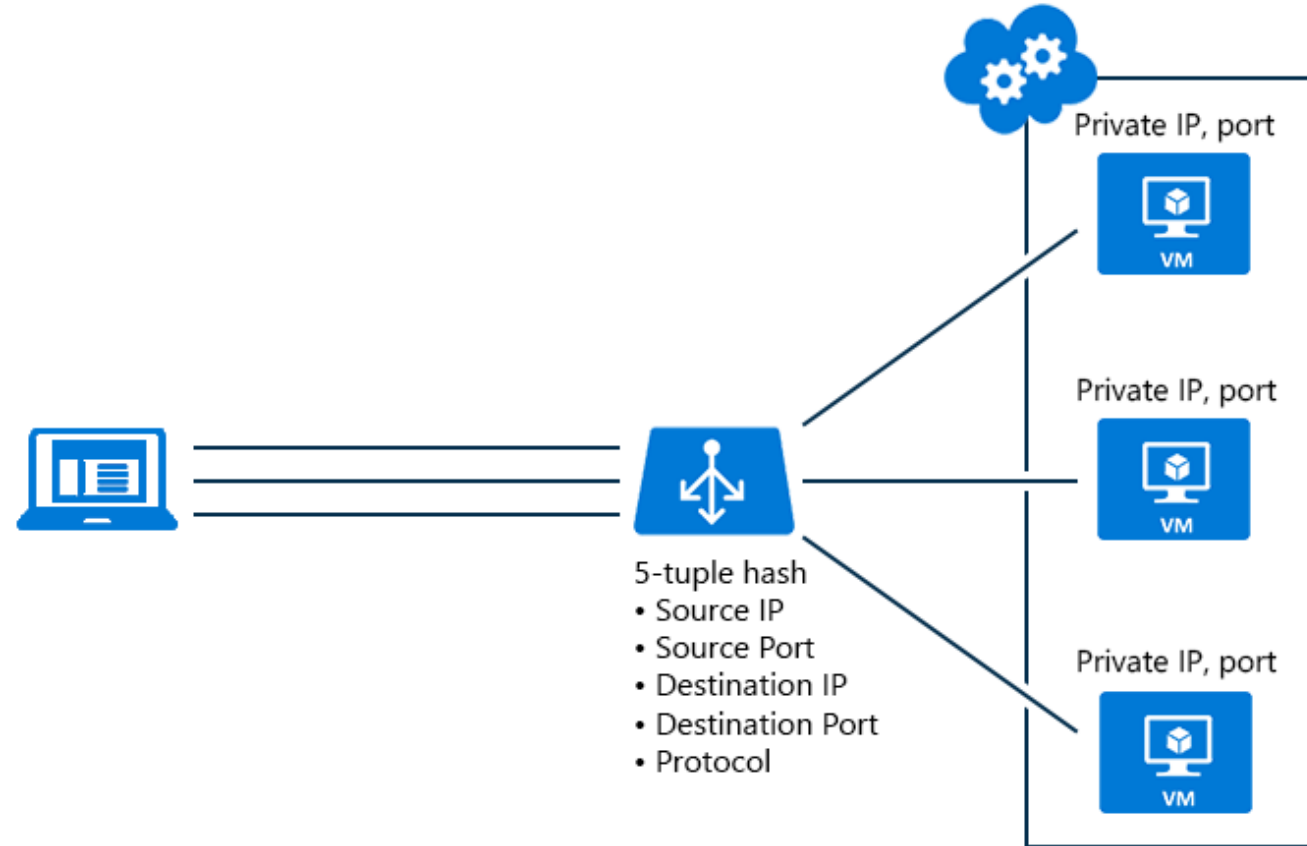

# Azure Public IP Address SKUs

---

Basic	Standard
Original PIP	New public IP tier
Dynamic or Static Allocation	Static Allocation
Open by default	Closed by default(requires NSG)
nNIC,VPN Gateway, Application Gateway, Public Load Balancer	Same resource
Not zone-redundant	Availability zone aware

# Azure Load Balancer

# Azure Load Balancer

- With Azure Load Balancer, you can create a load-balancing rule to distribute traffic that arrives at frontend to backend pool instances.
- Load Balancer uses a hash-based algorithm for distribution of inbound flows and rewrites the headers of flows to backend pool instances accordingly.
- Port forwarding
  - With Load Balancer, you can create an inbound NAT rule to port forward traffic from a specific port of a specific frontend IP address to a specific port of a specific backend instance inside the virtual network.
- Application agnostic and transparent
  - Load Balancer does not directly interact with TCP or UDP or the application layer, and any TCP or UDP application scenario can be supported. Load Balancer does not terminate or originate flows, interact with the payload of the flow, provides no application layer gateway function, and protocol handshakes always occur directly between the client and the backend pool instance.

# Azure Load Balancer

- Automatic reconfiguration
  - Load Balancer instantly reconfigures itself when you scale instances up or down. Adding or removing VMs from the backend pool reconfigures the Load Balancer without additional operations on the Load Balancer resource.
- Health probes
  - To determine the health of instances in the backend pool, Load Balancer uses health probes that you define. When a probe fails to respond, the Load Balancer stops sending new connections to the unhealthy instances. Existing connections are not affected, and they continue until the application terminates the flow, an idle timeout occurs, or the VM is shut down.
- Outbound connections (SNAT)
  - All outbound flows from private IP addresses inside your virtual network to public IP addresses on the internet can be translated to a frontend IP address of the Load Balancer. When a public front end is tied to a backend VM by way of a load balancing rule, Azure programs outbound connections to be automatically translated to the public frontend IP address.

# Demo

## Azure Load Balancer

# Azure Traffic Manager

- Azure Traffic Manager is a DNS-based traffic load balancer that enables you to distribute traffic optimally to services across global Azure regions, while providing high availability and responsiveness.

# Traffic Manager Routing Methods

- **Priority:** Select Priority when you want to use a primary service endpoint for all traffic, and provide backups in case the primary or the backup endpoints are unavailable.
- **Weighted:** Select Weighted when you want to distribute traffic across a set of endpoints, either evenly or according to weights, which you define.
- **Performance:** Select Performance when you have endpoints in different geographic locations and you want end users to use the "closest" endpoint in terms of the lowest network latency.
- **Geographic:** Select Geographic so that users are directed to specific endpoints (Azure, External, or Nested) based on which geographic location their DNS query originates from. This empowers Traffic Manager customers to enable scenarios where knowing a user's geographic region and routing them based on that is important. Examples include complying with data sovereignty mandates, localization of content & user experience and measuring traffic from different regions.
- **Multivalue:** Select MultiValue for Traffic Manager profiles that can only have IPv4/IPv6 addresses as endpoints. When a query is received for this profile, all healthy endpoints are returned.
- **Subnet:** Select Subnet traffic-routing method to map sets of end-user IP address ranges to a specific endpoint within a Traffic Manager profile. When a request is received, the endpoint returned will be the one mapped for that request's source IP address.
